## INDUSTRIAL ROBOT WITH ORIGIN ADJUSTING MEANS.

(57)

An articulated industrial robot has origin adjusting recesses (11a, 12a, 12b, 13a, 13b, 14a, 14b, 15a, 16a, 16b and 26a) formed at the rotatable interconnection between a fixed trunk component (11) and a rotatable trunk component (12), the rotatable interconnection between the rotatable trunk component (12) and a first arm (13), the rotatable interconnection between the first arm (13) and a second arm (14), the rotatable interconnection between the second arm (14) and a wrist proximal region (15) and the interconnection between the wrist proximal region (15) and a wrist distal region (16), and gauges (20, 21, 22, 23, 24, 25, 26, 27 and 28) respectively fitted in the above-described recesses, thereby allowing a visual and accurate origin adjustment.

EP 0 166 002 A1

DESCRIPTION

TITLE OF THE INVENTION

INDUSTRIAL ROBOT WITH ORIGIN ADJUSTING MEANS

TECHNICAL FIELD

The present invention relates to an articulated  
5 type industrial robot, more particularly to an industrial  
robot with an origin adjusting means.

BACKGROUND ART

Generally, an industrial robot has a plurality of  
robot components, such as a rotary body, an arm and a  
10 wrist, which are joined by means of joints for relative  
rotation about the axes of the respective joints. The  
respective motions of these robot components are con-  
trolled numerically according to a program taught  
beforehand to the robot for the desired motion of the  
15 output end thereof provided at the extremity of the  
wrist thereof.

Since the program for the numerical control of a  
robot is designed on the basis of the original position  
of each articulating joint, the joints of the robot must  
20 be positioned at the original positions, in teaching the  
program to the robot or in making the robot execute the  
program. Nevertheless, it has been a conventional  
procedure to position each articulating joint of a robot  
at the original position by turning or revolving the  
25 components of the robot and adjusting the angle between  
the components through eye measurement without employing  
any positive origin adjusting means. Accordingly, such  
origin adjustment has been unsatisfactory in respect of  
positioning accuracy and repeatability.

30 DISCLOSURE OF THE INVENTION

Accordingly, it is an object of the present inven-  
tion to provide an industrial robot provided with origin  
adjusting means capable of eliminating the above-men-  
tioned disadvantages of the conventional industrial  
35 robot.

It is another object of the present invention to provide an articulated type robot integrally having an origin adjusting means provided at each articulating joint thereof.

5       The objects of the present invention are achieved by an industrial robot comprising: a stationary body unit having a first reference recess formed at a fixed position to receive a first gauge member removably therein; a rotary body unit disposed on the stationary  
10 body unit so as to be rotatable about the longitudinal axis thereof, having a second reference recess formed at a fixed position which approaches the first reference recess when the rotary body unit is turned relative to the stationary body unit and positioned at an original  
15 position, to receive removably a second gauge member which cooperates with the first gauge member, and a third reference recess formed at another fixed position to receive a third gauge member removably therein; a first arm mounted on the rotary body unit so as to be  
20 rotatable about a first transverse axis extending perpendicularly to the longitudinal axis of the rotary body unit, and having a fourth reference recess formed at a fixed position which approaches the second reference recess when the first arm is turned relative to the  
25 rotary body unit and positioned at a fixed original position, to receive removably a fourth gauge member which cooperates with the third gauge member, and a fifth reference recess formed at another fixed position to receive a fifth gauge member therein removably; a  
30 second arm attached to the first arm so as to be rotatable about a second transverse axis extending in parallel to the first transverse axis, and having a sixth reference recess formed at a fixed position which approaches the fifth reference recess when the second  
35 arm is turned relative to the first arm and positioned at a fixed original position, to receive removably a sixth gauge member which cooperates with the fifth gauge

member, and a seventh reference recess formed at another fixed position to receive a seventh gauge member therein removably; a base wrist unit attached to the second arm so as to be rotatable about a third transverse axis  
5 extending in parallel to the second transverse axis, and having an eighth reference recess formed at a fixed position which approaches the seventh reference recess when the base wrist unit is turned relative to the second arm and positioned at a fixed original position  
10 to receive removably an eighth gauge member which cooperates with the seventh gauge member; and a fore wrist unit attached to the base wrist unit so as to be rotatable about a fourth transverse axis extending perpendicularly to the third transverse axis, and having  
15 holes formed therein to hold removably a ninth gauge member which cooperates with the eighth gauge member seated in the eighth reference recess, when the fore wrist unit is turned relative to the base wrist unit and positioned at a fixed original position. Furthermore,  
20 the present invention provides an articulated type industrial robot having a plurality of rotary joints; a pair of origin adjusting recesses formed in the two members joined by each rotary joint, so as to be brought into alignment with each other; and a pair of gauge  
25 members each having a sharp point and capable of being removably fitted in a pair of the origin adjusting recesses formed in the two members joined by each rotary joint, whereby the origin of each rotary joint is adjusted by positioning the rotary joint at an original  
30 position so that the respective sharp points of a pair of the gauge members fitted in the origin adjusting recesses respectively coincide with each other.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic side elevation of an  
35 articulated type industrial robot with original adjusting means, according an embodiment of the present invention;

Fig. 2 is a fragmentary perspective view showing

portions of the stationary body unit and the rotary body unit of the robot of Fig. 1;

Fig. 3 is a perspective view of gauge members to be used on the stationary body unit and the rotary body unit of the robot of Fig. 1;

Fig. 4 is a fragmentary perspective view of the rotary body and the first arm of the robot of Fig. 1;

Fig. 5 is a fragmentary perspective view showing the respective portions around the joint of the first arm and the second arm of the robot of Fig. 1;

Fig. 6 is a fragmentary perspective view showing the front end and its vicinity to the second arm of the robot of Fig. 1; and

Fig. 7 is a perspective view showing gauge members to be applied to the second arm and the base wrist unit and gauge members to be applied to the base wrist unit and the fore wrist units.

#### BEST MODE FOR CARRYING OUT THE INVENTION

Referring to Fig. 1, an articulated type industrial robot having five rotary joints comprises a stationary body unit 11, a rotary body unit 12, a first arm 13, a second arm 14, a base wrist unit 15 and a fore wrist unit 16 as mechanical components. The fore wrist unit 16 functions as an output unit of the robot and is adapted to be mounted thereon, for example, with a robot hand, not shown. The rotary body unit 12 is joined to the stationary body unit 11 by a first rotary joint so as to be rotatable relative to the stationary body unit about a longitudinal axis (Z-axis) aligned with the center axis of the stationary body unit 11. The rotary body unit 12 is driven for rotation by a motor 17 mounted on the base of the stationary body unit 11. The first arm 13 is joined to the rotary body unit 12 by a second rotary joint so as to be rotatable about a first transverse axis (W-axis) extending perpendicularly to the Z-axis. The first arm is driven for rotation by a motor 18 attached to the side surface of the rotary body unit

12. The second arm 14 is joined to the first arm 13 by a third rotary joint so as to be rotatable about a second transverse axis (U-axis) extending in parallel to the W-axis. The second arm is driven for rotation by a motor, not shown in Fig. 1, attached to the other side surface of the rotary body 12 opposite the side surface to which the motor 18 is attached. The base wrist unit 15 is joined to the second arm 14 by a fourth rotary joint so as to be rotatable about a third transverse axis ( $\beta$ -axis) extending in parallel to the U-axis. The base wrist unit is driven for rotation by a motor 19 attached to the rear end of the second arm 14. The fore wrist unit 16 is joined to the base wrist unit 15 by a fifth joint so as to be rotatable about a fourth transverse axis ( $\alpha$ -axis) extending perpendicularly to the  $\beta$ -axis. The fore wrist unit is driven for rotation by a motor, not shown in Fig. 1, attached to the rear end of the second arm 14 opposite to the motor 19. Origin adjusting means will be described hereinafter with reference to Figs. 2 to 7.

As shown in Fig. 2, a pair of recesses 11a and 12a are formed in the continuous portions of the stationary body unit 11 and the rotary body unit 12, respectively. The recess 11a is a slot formed in the upper end surface of the stationary body unit 11 so as to extend perpendicularly to the Z-axis. The slot-formed recess 11a is capable of receiving a plate gauge 20 as shown in Fig. 3 by slidable fitting. The other recess 12a is a hole formed in the side surface of the rotary body unit 12. A pin gauge 21 as shown in Fig. 3 can be removably fitted in the hole formed recess 12a. A pair of the gauges 20 and 21 have sharp ends 20a and 21a, respectively. A pair of the recesses 11a and 12a are located so that the sharp ends 20a and 21a of a pair of the gauges 20 and 21 fitted in the recesses 11a and 12a respectively coincide with each other when the rotary body 12 is at an original position with respect to the

stationary body unit 11. Accordingly, the origin of the rotary body unit can be adjusted by making the sharp end 21a of the pin gauge 21 coincide with the sharp end 20a of the plate gauge 20. Since the recesses 11a and 12a for origin adjustment can be formed beforehand in machining the stationary body unit 11 and the rotary body unit 12 at positions determined from datum planes respectively, the recesses 11a and 12a can be accurately positioned.

10 As shown in Fig. 4, a pair of recesses 12b and 13a are formed in the contiguous portions of the rotary body unit 12 and the first arm 13, respectively. The recess 12b is a slot formed in the upper surface of the rotary body unit 12 so as to extend in parallel to the W-axis.

15 The slot-formed recess 12b is capable of receiving a plate gauge, not shown, similar to the plate gauge 20 shown in Fig. 3 by slidable fitting. The other recess 13a is a hole formed in the side surface of the first arm 13 which is capable of removably receiving a gauge, not shown, similar to the pin gauge 21 shown in Fig. 3.

20 A pair of the recesses 12b and 13a are located so that the sharp ends of a pair of the gauges fitted in the pair of recesses 12b and 13a, respectively, coincide with each other when the first arm 13 is at an original position of the turning motion thereof with respect to the rotary body unit 12. Accordingly, the origin of the first arm 13 can be adjusted by making the sharp end of the pin gauge coincide with the sharp end of the plate gauge. The recesses 12b and 13b for origin adjustment

25 can be formed beforehand during machining of the rotary body unit 12 and the first arm 13 at positions determined from datum planes respectively, and hence the recesses 12b and 13a can be accurately positioned.

30 As shown in Fig. 5, a pair of recesses 13b and 14a are formed in the contiguous portions of the first arm 13 and the second arm 14 respectively. The recess 13b is a slot formed in the upper surface of the first

arm 13. The slot-formed recess 13b extends in parallel to the U-axis. The slot-formed recess 13b is capable of receiving a plate gauge 22 by slidable fitting. The other recess 14a is a slot formed in the upper surface of the second arm 14 so as to extend in parallel to the U-axis. The slot-formed recess 14a is capable of removably receiving a plate gauge 23. The plate gauges 22 and 23 have sharp ends 22a and 23a respectively. A pair of recesses 13b and 14a are located so that the sharp ends 22a and 23a of the pair of plate gauges 22 and 23 fitted in the recesses 13b and 14a respectively coincide with each other when the second arm 14 is positioned at an original position with respect to the first arm 13. Accordingly, the origin of the second arm 14 can be adjusted by making the sharp end 23a of the plate gauge 23 coincide with the sharp end 22a of the plate gauge 22. Since the recesses 13b and 14a can be formed beforehand during machining of the first arm 13 and the second arm 14 from datum planes respectively, the recesses 13b and 14a can be accurately positioned.

As shown in Fig. 6, a pair of recesses 14b and 15a are formed in the contiguous portions of the second arm 14 and the base wrist unit 15, respectively. The recess 14b is a slot formed in the front end surface of the second arm 14 so as to extend in parallel to the  $\beta$ -axis. The slot-formed recess 14b is capable of receiving a plate gauge 24 shown in Fig. 7 by slidable fitting. The other recess 15a is a slot formed in the side surface of the base wrist unit 15 so as to extend in parallel to the  $\alpha$ -axis in this embodiment. A plate gauge 25 shown in Fig. 7 can be fitted in the slot-formed recess 15a. The plate gauges 24 and 25 have sharp ends 24a and 25a respectively. The pair of recesses 14b and 15a are located so that the sharp ends 24a and 25a of the plate gauges 24 and 25 fitted in the recesses 14b and 15a, respectively, coincide with each other when the

base wrist unit 15 is positioned at an original position with respect to the second arm 14. Accordingly, the origin of the base wrist unit 15 can be adjusted by making the sharp end 25a of the plate gauge 25 coincide with the sharp end 24a of the plate gauge 24. The recesses 14b and 15a can be formed beforehand during machining of the second arm 14 and the base wrist unit 15 at positions determined from datum planes, respectively, and hence the recesses 14b and 15a can be accurately positioned.

In the portion of the fore wrist unit 16 contiguous to the base wrist unit 15, the fore wrist unit 16 is provided with recesses 16a and 16b, which are reamed holes or threaded holes. A gauge 26 having pins or screws which fit in the reamed holes or the threaded holes can be attached to the fore wrist unit 16. A pin gauge 27 shown in Fig. 7 can be removably fitted in a recess 26a, a reamed hole, formed in the gauge 26. On the other hand, the recess 15a is capable of receiving a plate gauge 28 shown in Fig. 7 by slidable fitting. The gauges 27 and 28 have sharp ends 27a and 28a. The recesses 16a, 16b and 26a are located so that the sharp ends 27a and 28a of the gauges 27 and 28 fitted in the recesses 15a and 26a coincide with each other when the fore wrist unit 16 is at an original position with respect to the base wrist unit 15. The recesses 16a and 16b can be formed beforehand at positions determined from a datum plate during machining of the fore wrist unit 16.

After assembling the industrial robot provided with the origin adjusting means of the above-mentioned constitution, the origin of each joint of the industrial robot is decided by fitting the corresponding gauges in the corresponding recesses for origin adjustment, and then gradually turning one of the corresponding pair of the robot components relative to the other to a position where the sharp ends of the corresponding pair of the

gauges coincide with each other as one of the corresponding pair of the gauges is slid for displacement. If the relative position between the adjacent robot components is deviated from a position corresponding to the origin of the corresponding joint, the sharp ends of the corresponding gauges overlap each other when one of the gauges is advanced toward the other. Therefore, misalignment of the gauges can be extremely precisely and readily recognized visually. Accordingly, the origin adjustment of the industrial robot can be extremely easily and highly accurately achieved.

After the completion of the origin adjustment, the gauges can be removed from the recesses.

Although the invention has been described with reference to a preferred embodiment thereof, it is obvious that the present invention is not limited to the preferred embodiment. For example, the present invention is applicable not only to the above-mentioned articulated type robot having five joints, but also to an articulated type robot having six joints, for instance. Furthermore, standardization of the form and size of the recesses enables the common use of a single gauge in several recesses. Still further, the morphology of the recesses formed in the robot and that of the gauges may be variously changed without departing from the scope of the invention determined by the appended claims.

CLAIMS

1. An industrial robot comprising:

a stationary body unit having a first reference recess formed at a fixed position to receive a first gauge member removably therein;

5 a rotary body unit disposed on said stationary body unit so as to be rotatable about the longitudinal axis thereof, having a second reference recess formed at a fixed position which approaches the first reference recess when the rotary body unit is  
10 turned relative to the stationary body unit and positioned at an original position, to receive removably a second gauge member which cooperates with said first gauge member, and a third reference recess formed at another fixed position to receive a third gauge member  
15 removably therein;

a first arm mounted on said rotary body unit so as to be rotatable about a first transverse axis extending perpendicularly to the longitudinal axis of said rotary body unit, and having a fourth reference  
20 recess formed at a fixed position which approaches said second reference recess when said first arm is turned relative to said rotary body unit and positioned at a fixed original position, to removably receive a fourth gauge member which cooperates with said third gauge  
25 member, and a fifth reference recess formed at another fixed position to removably receive a fifth gauge member therein;

a second arm attached to said first arm so as to be rotatable about a second transverse axis  
30 extending in parallel to said first transverse axis, and having a sixth reference recess formed at a fixed position which approaches said fifth reference recess when said second arm is turned relative to said first arm and positioned at a fixed original position, to  
35 removably receive a sixth gauge member which cooperates with said fifth gauge member, and a seventh reference

recess formed at another fixed position to removably receive a seventh gauge member therein;

a base wrist unit attached to said second arm so as to be rotatable about a third transverse axis  
5 extending in parallel to said second transverse axis, and having an eighth reference recess formed at a fixed position which approaches said seventh reference recess when said base wrist unit is turned relative to said second arm and positioned at a fixed original position  
10 to removably receive an eighth gauge member which cooperates with said seventh gauge member, and;

a fore wrist unit attached to said base wrist unit so as to be rotatable about a fourth transverse axis extending perpendicularly to said third  
15 transverse axis, and having holes formed therein to removably hold a ninth gauge member which cooperates with said eighth gauge member received in said eighth reference recess, when said fore wrist unit is turned relative to said base wrist unit and positioned at a  
20 fixed original position.

2. An industrial robot according to Claim 1, wherein said first reference recess is formed in an upper end of said stationary body unit and said second reference recess is formed in a lower portion of said  
25 rotary body unit contiguous to said upper end of said stationary body unit.

3. An industrial robot according to Claim 1, wherein said third reference recess is formed in a top of said rotary body unit and said fourth reference  
30 recess is formed in one end of said first arm contiguous to said top of said rotary body unit.

4. An industrial robot according to Claim 3, wherein said fifth reference recess is formed at the other end of said first arm and said sixth reference  
35 recess is formed in a rear part of said second arm contiguous to said other end of said first arm.

5. An industrial robot according to Claim 1,

wherein said seventh reference recess is formed in said front end of said second arm and said eighth reference recess is formed in said front end of said base wrist unit contiguous to said front end of said second arm.

5       6.    An industrial robot according to Claim 1, wherein each of said first to said ninth gauge members has a sharp end which can be brought into coincidence with a sharp end of an associated gauge member with which the former cooperates.

10       7.    An articulated type industrial robot having a plurality of rotary joints each provided with a pair of recesses capable of being aligned with each other for origin adjustment and a pair of gauge members capable of being removably fitted in a pair of the recesses for  
15   origin adjustment and each having a sharp end, characterized in that said sharp ends of said pair of gauge members fitted in the paired recesses are brought into coincidence with each other for origin adjustment of the corresponding rotary joint when said corresponding  
20   rotary joint is positioned at the origin thereof.

      8.    An articulated type industrial robot according to Claim 7, wherein a pair of recesses for origin adjustment of each of the rotary joints are formed integrally with the corresponding adjacent components of  
25   the rotary joint.
